Temporal Bone Specimen Handling Protocol

This protocol describes how cadaveric temporal bone specimens are stored and scanned before micro-slicing. Specimens are fixed in formalin and kept refrigerated until imaging.

Storage conditions

Step	Temperature	Maximum duration
Fixation	4 °C	14 days
Storage before CBCT	4 °C	30 days
Resin embedding	21 °C	3 days

Imaging

Cone-beam CT is acquired before and after resin embedding with an isotropic voxel size of 0.125 mm. Each scan is checked for motion artefacts before the specimen is released for micro-slicing.
